#### A. BASIC CONCEPTS

This study summarizes the population projections by age, sex, and marital status used for the analysis of potential future financial commitments of the Old-Age and Survivors Insurance and Disability Insurance Trust Funds appearing in the 1983 Report of the Board of Trustees. These population projections supersede those published in Actuarial Study No. 85, which were used in the 1981 and 1982 Reports of the Board of Trustees. These new projections reflect an updated estimate of the starting population which is based on the results from the 1980 census; more recent data on fertility, mortality, marriage, and divorce; and slightly revised projections of mortality and fertility. Considerably more detail than is published in this study is available from the Office of the Actuary, upon request.

The population projections in this study were developed from an estimate of the starting population in the Social Security Area by age, sex, and marital status and of existing marriages by age of husband and age of wife; and assumptions about future net immigration, births, deaths, marriages, and divorces. For estimates of the population and of existing marriages, we relied upon the Bureau of the Census. However, it was necessary to make modifications to the U.S. resident population to account for net census undercount and for persons outside the fifty States and the District of Columbia who are covered by Social Security. For data on immigration, we relied upon the Immigration and Naturalization Service. For data on births, deaths, marriages, and divorces we relied upon the National Center for Health Statistics.

Because the components of population change (with the exception of net immigration) depend heavily upon the size of the population, it is better to analyze them as rates than as absolute numbers. The rates discussed in this study are generally annual central rates, that is, the number of occurrences of an event during a year as a ratio to the mid-year population having the potential to experience the event. Because marriage is the combination of a male and a female into a couple, marriage rates can be computed as a ratio to (1) the number of nonmarried males (not taking into account the number of nonmarried females), (2) the number of nonmarried females (not taking into account the number of nonmarried males), or (3) a theoretical number of nonmarried couples that does take into account both the number of nonmarried males and nonmarried females. The central marriage rates used in this study are computed under the third concept of a theoretical number of nonmarried couples. The rates were computed as the number of marriages for given ages of husband and wife divided by the square root of the product of the mid-year nonmarried males and nonmarried females of the given ages. Because death rates vary by sex, they are calculated for each sex separately. Because rates of birth, death, marriage, and divorce vary greatly by age, it is better to analyze them on an age-specific basis (each age separately) than on a crude basis (all ages combined). A compromise sometimes used in this study is to analyze rates by five-year age groups rather than single ages. The population bases used to calculate age-specific central rates of birth, death, marriage and divorce were obtained from the Bureau of the Census, with modifications as needed.

Although analyzing components of population change on an age-specific basis generally yields high accuracy, it also generates more figures than the mind can easily assimilate. Hence to study trends through time, it is conceptually convenient, if not necessary, to summarize each component of change by a single statistic.

Because within each sex the number of deaths depends upon the age distribution of the population, a summarizing statistic for mortality is customarily calculated as a weighted average of the age-specific death rates, where the weightings are the relative sizes of the age-specific populations in some standard population. This rate, called the age-adjusted death rate, when multiplied by the standard population, gives the number of deaths that would occur in the standard population if the age-specific death rates were to be experienced. It is thus equivalent to the crude rate that would be experienced in the standard population. Age-sex-adjusted death rates are often calculated when one is interested in summarizing death rates for both sexes combined. Age-adjusted death rates and age-sex-adjusted death rates are generally expressed per hundred thousand.

Because the number of births depends upon the age distribution of the female population of childbearing age, a summarizing statistic for fertility might be calculated by age-adjustment to a standard female population of childbearing age. However, a simple sum of the age-specific birth rates expressed per thousand is generally used, because it is more easily interpreted. This statistic, called the total fertility rate, gives the number of children that would be born to a thousand women if they were to survive the childbearing years and were to experience the current age-specific birth rates throughout those years. Sometimes, the total fertility rate is expressed per woman, rather than per thousand women.

The number of marriages depends upon the age distribution of both the nonmarried male population and the nonmarried female population. Thus, an acceptable summarizing statistic could be calculated by age-adjustment to a set of standard nonmarried populations. When only one population is involved in the rates (e.g., death rates), age-adjusting can be thought of as either the weighted average of the age-specific rates or as the crude rate that would occur in the standard population. When two populations are involved in the rates (as in marriage rates), these two concepts lead to two slightly different, although equally useful, formulas. In either case, the number of marriages that would occur in the standard population is first calculated by applying the age\*of\*husband-age\*of\*wife-specific marriage rates to the square root of the product of the corresponding standard age-specific populations. The weighted average of the rates is obtained by dividing the resulting total number of marriages by the sum of all of the factors to which the marriage rates were applied, while the crude rate is obtained by dividing the total number of marriages by the square root of the product of the total male nonmarried population and the total female nonmarried population. We have calculated these rates, which we express per hundred thousand

nonmarried of each sex, for the years 1957 through 1979. In this study, age-adjusted marriage rates will refer to the later concept, i.e., the crude rate that would be experienced in the standard population.

The number of divorces depends upon the age\*of\*husband-age\*of\*wife distribution of the married population. Thus, an acceptable summarizing statistic could be calculated by age-adjustment to a standard married population. Such a statistic has not been computed, however, because highly reliable data through time on divorces by age of husband and age of wife are difficult to obtain and even more difficult to match with accurate estimates of the population eligible to be divorced.

## B. ASSUMPTIONS

### 1. Starting Population

The starting population for the projections was the estimated population in the Social Security Area as of July 1, 1981 by single years of age, sex, and marital status. The components of the Social Security Area and the estimated population of each component (in thousands) are as follows:

Residents of the fifty States and D.C.	
and armed forces overseas.....	229,803
Adjustment for net census undercount.....	4,368
Civilian residents of Puerto Rico.....	3,248
Civilian residents of the Virgin Islands.....	99
Civilian residents of Guam.....	101
Civilian residents of American Samoa.....	33
Federal civilian employees overseas.....	42
Dependents of Federal employees overseas.....	385
Crew members of merchant vessels.....	19
Other citizens overseas.....	490
Total.....	238,588

The number of residents of the fifty States and D.C. and armed forces overseas was published by the Bureau of the Census by sex, by single years of age up to age 85, and for ages 85 and over in Current Population Reports Series P-25, No. 917. The numbers of persons in the other components of the Social Security Area were estimated by sex, by single years of age up to age 85, and for ages 85 and over from various data sources. The age distribution of those aged 85 and over in the starting population was assumed to be the same as that in the population enrolled under the Medicare program as of January 1, 1981. The adjustment for net census undercount was estimated from data published in Current Population Reports Series P-23, No. 115. The numbers of civilian residents of Puerto Rico, the Virgin Islands, Guam, and American Samoa were estimated from data published by the Bureau of the Census in Current Population Reports Series P-25, No. 919. The numbers of Federal civilian employees overseas and dependents of Federal civilian employees and of armed forces overseas were estimated from data supplied by the State Department and the Office of Personnel Management. The number of crew members of merchant vessels was estimated from data obtained from the Maritime Administration. The number of other citizens overseas covered by Social Security was estimated from data supplied by the State Department. The overlap among the components, believed to be small, was ignored. Table 1 gives the July 1, 1981 Social Security Area population by age group, sex, and component.

The distribution of the starting population by marital status (never married, currently married, currently widowed, and currently divorced) was estimated by age and sex from data published by the Bureau of the Census in Current Population Reports Series P-20, No. 372. A distribution of the starting married population by age of husband crossed with age of wife was estimated from data published by the Bureau of the Census in 1970 Census of Population Subject Report on Marital Status No. PC(2)-4C. The distribution as shown in the 1970 census was adjusted to represent 1981 by an iterative proration method designed to assure consistency with the previously estimated starting married population by age and sex. Table 2 shows the starting population in the Social Security Area by age group, sex, and marital status. Table 3 shows the starting married population by age group of husband crossed with age group of wife.

## 2. Fertility

As a first step in projecting fertility, it is instructive to examine the recent history of fertility in the United States. During the period 1917 to 1925, the total fertility rate was more than three children per woman. During the period 1924-1933 the total fertility rate declined from 3.1 to 2.2 children per woman, and then remained level at 2.1-2.2 children per woman through 1940. During the next twenty years, the total fertility rate increased unsteadily to more than 3.6 children per woman. Throughout the 1960's and early 1970's, the total fertility rate declined steadily to a low point of 1.7 in 1976. Since then, the total fertility rate has been about 1.8 children per woman.

We believe that the total fertility rate will eventually increase above the present low level, but that it will not return to the high levels observed during the late 1940's, 1950's and early 1960's. We believe that the total fertility rate will ultimately exceed the present low level because such a total fertility rate has never been experienced in the United States until recently, and because such a total fertility rate is well below that needed to replenish the population. We believe that the total fertility rate will not return to the high levels observed in the past because of the increasing tendency to view children more as economic liabilities than as assets, because of the increase in contraception and abortion, because of the increasing attachment of women to the labor force, because of the increasing prevalence of divorce, and because of the increased tendency toward postponement of marriage among young women. Current birth expectation surveys, such as that published by the Bureau of the Census in Current Population Reports Series P-20, No. 378 are consistent with a long-range assumption for the total fertility rate in the neighborhood of 2.0-2.1 children per woman. As the intermediate (alternative II) assumption for the 1983 Report of the Board of Trustees, we have used an ultimate total fertility rate of 2.0 children per woman.

A comparison of the total fertility rate in 1976 in the U.S., Canada, and fifteen countries in Western Europe reveals a range from 3.5 in Ireland to 1.5 in Germany. The U.S. ranked eighth with 1.75. These data, which are published in Current Population Reports Series P-23, No. 123, show four countries with a total fertility rate over 2.3 and two countries with a total fertility rates under 1.6. For reasons already cited, we do not believe that the total fertility rate will return to such a high level as 3.5, and have selected 2.3 as our alternative I assumption. Because of the great changes in the roles of women in our society and because of a possible increase in the use of readily available methods of contraception, the total fertility rate in the U.S. could, over a long period of time, drop below the 1.7 experienced in 1976. We have selected 1.6 as our alternative III assumption. These ultimate values can be compared with those used by the Bureau of the Census in its latest series of population projections, which are published in Current Population Reports, Series P-25, No. 922. The Bureau of the Census used a range of 1.6 to 2.3, with an intermediate assumption of 1.9. A rate of 2.1 would result in a nearly constant population if there were no migration and if mortality rates were constant. The ultimate total fertility rate for each alternative was assumed to be first reached in calendar year 2007.

Total fertility rates for 1980 through 1982 were estimated from provisional data published by the National Center for Health Statistics in Monthly Vital Statistics Reports Volumes 29 through 31. Between 1982 and 2007, the age-specific birth rates were projected separately for each cohort of women such that the completed cohort fertility rate would gradually approach the ultimate total fertility rate. Table 5 gives past and assumed total fertility rates by alternative. Chart 1 shows past and assumed total fertility rates for 1920-2080. Tables 4 give the assumed age-specific central birth rates by alternative for selected calendar years.

### 3. Mortality

Any creditable attempt at projecting death rates must begin with a study of past trends in mortality. An examination of central death rates (age-adjusted to the enumerated population of the United States as of April 1, 1970) reveals four distinct periods of diverse mortality improvement since 1900. During the period 1900-1936, annual mortality improvement averaged about 0.9 percent for males and 1.0 percent for females. Following this was a period of rapid improvement, 1936-1954, in which mortality improved an average of 1.7 percent per year for males and 2.6 percent per year for females. The period 1954-1968 saw an actual deterioration for males of 0.1 percent per year and a much slower improvement of 0.8 percent per year for females. From 1968 through 1981 rapid improvement in mortality resumed, averaging 1.8 percent for males and 2.2 percent for females, annually. The central death rates for 1980 and 1981 were estimated from provisional statistics. They show a significant increase in mortality in 1980 which is more than offset by an even greater decline in 1981.

Past improvement in mortality has varied greatly by cause of death. Because it is expected that future improvement in mortality will also vary greatly by cause of death, we analyzed central death rates by age group and sex for ten groups of causes of death. These groups are as follows:

- I. Diseases of the Heart (Eighth Revision of the International List of Diseases and Causes of Death code numbers 390-398, 402, 404, 410-429)
- II. Malignant Neoplasms (140-209)
- III. Vascular Diseases (400-401, 403, 430-458, 582-584)
- IV. Accidents, Suicide, and Homicide (E800-E989)
- V. Diseases of the Respiratory System (460-519)
- VI. Congenital Malformations and Diseases of Early Infancy (740-778)
- VII. Diseases of the Digestive System (520-570, 572-577)
- VIII. Diabetes Mellitus (250)
- IX. Cirrhosis of the Liver (571)
- X. All Other Causes

Central death rates were obtained from the National Center for Health Statistics for each calendar year in the period 1968-1978 by age group, sex and cause of death. Average annual improvements in mortality were calculated as the complement of the exponential of the slope of the least-squares line through the logarithms of the central death rates, and are shown in Table 6. The sharpest improvement was in Congenital Malformations and Diseases of Early Infancy, averaging over 5 percent per year. Averaging from about 3 to about 4 percent per year were Vascular Disease, Digestive Disease, and Diabetes Mellitus. From about 2 to 2 1/2 percent improvement per year were Heart Disease, Respiratory Disease, and Violence. Cirrhosis of the Liver and the residual group of Other Causes averaged 1/2 to 1 percent annual improvement. Cancer was the only group of causes that showed a deterioration, increasing by about 1/2 percent per year.

Future improvements in mortality will depend upon such factors as the development and application of new diagnostic and surgical techniques, the presence of environmental pollutants, improvements in exercise and nutrition, the incidence of violence, the isolation and treatment of causes of disease, the appearance of new diseases (such as AIDS), improvements in prenatal care, the incidence of abortion, the prevalence of cigarette smoking, the misuse of drugs (including alcohol), the extent to which people assume responsibility for their own health, and changes in our conception of the value of life. After considering how these and other factors might affect mortality, we postulated a set of ultimate annual percentage improvements in central death rates for each alternative by sex and cause of death. These ultimate annual percentage improvements are as follows:

Assumed Ultimate Annual Percentage Improvements in Central Death  
Rates by Alternative, Sex, and Causes

---

Alternative and Sex	Group of Causes of Death									
	I	II	III	IV	V	VI	VII	VIII	IX	X
<b>Alternative I</b>										
Male	0.5	0.0	0.7	0.0	0.0	0.7	0.4	0.2	0.0	0.1
Female	0.5	0.0	0.7	0.0	0.0	0.7	0.4	0.2	0.0	0.1
<b>Alternative II</b>										
Male	0.7	0.2	0.9	0.0	0.1	1.0	0.7	0.4	0.2	0.3
Female	0.7	0.3	0.9	0.0	0.2	1.0	0.7	0.5	0.2	0.3
<b>Alternative III</b>										
Male	1.0	1.2	1.2	0.0	0.3	1.5	1.0	0.8	0.5	0.5
Female	1.0	1.5	1.5	0.0	0.5	1.5	1.0	1.0	0.5	0.5

---

We assumed that improvement in mortality will continue to shift from infectious diseases (such as poliomyelitis and influenza), where very little additional improvement is possible, to degenerative diseases (such as heart and vascular disease), where much can yet be done. We assumed that infant mortality would continue to improve rapidly. A greater range of ultimate rates of improvement were assumed for cancer, because its death rate has actually been increasing recently and its future course seems less certain. Because a death rate that increases exponentially over a long period of time may lead to unacceptable results, none of the postulated ultimate rates of improvement are negative. In alternative I, the ultimate rates of improvement were the same for males and females. In alternatives II and III, the ultimate rates of improvement for some of the causes were assumed to be higher for women than for men. Thus, the gap between male and female mortality is assumed to continue to widen, but at a decreased rate, as women become increasingly subject to the same environmental pressures and hazards as men.

Central death rates by age group, sex, and cause of death for 1979 were estimated from provisional data published by the National Center for Health Statistics in Monthly Vital Statistics Reports Volume 28. Death rates for 1980 and 1981 were assumed to change from 1979 by amounts estimated from data published in Monthly Vital Statistics Reports Volumes 29 and 30. Central death rates were projected by age group, sex, and cause of death from their estimated 1981 levels by applying annual percentage improvements. The annual improvements applied during 1981-1982 were 50 percent, 100 percent, and 150 percent of the average annual improvements for 1968-1978 for alternatives I, II, and III, respectively. The assumed annual improvements applied during 1982-2007 were calculated by a logarithmic formula designed to gradually transform the improvement for 1981 to 1982 into the postulated ultimate annual improvements. The ultimate improvements were applied during 2007-2080. Tables 7 give the resulting central death rates by age group, sex, and alternative for selected years.

Tables 8 give life expectancies at birth and at age 65 by sex and alternative which are consistent with the projected death rates. Charts 2 show the past and projected life expectancies of males and females at birth from 1900 to 2080 by alternative. Under all three alternatives, the life expectancy at birth and at age 65 is projected to increase significantly. For males, the life expectancy at birth increases from 70.3 years in 1981 to 73.9 years, 77.2 years, and 83.3 years in 2080 under alternatives I, II, and III, respectively. This represents an increase ranging from 3.6 years to 13.0 years. For females the increase ranges from 4.0 years to 14.1 years over the 77.8 years in 1981, to 81.8 years, 85.5 years, and 91.9 years in 2080 under alternatives I, II, and III, respectively. The difference between male and female life expectancies is projected to increase from 7.5 years in 1981 to 7.9 in 2080 under alternative I, 8.3 under alternative II, and 8.6 under alternative III. The life expectancy at age 65 is projected to increase from 15 percent under alternative I to 65 percent under alternative III for males, and from 17 percent to 60 percent for females.

Although a complete projection of age-sex-specific death rates was not done for each marital status, we felt that it was important to reflect some differential in mortality by marital status. Future relative differences in death rates by marital status were assumed to be as experienced during 1959-1961. These rates were published by the National Center for Health Statistics in Vital and Health Statistics Series 20, Nos. 8a and 8b, and with some modifications are given in Table 9. We hope that a study to be published based on the 1980 Census will provide us with more recent data for our next set of projections.

#### 4. Net Immigration

Immigration was once a very important element in the growth of the United States population. During calendar years 1904 through 1913 for example, immigration averaged nearly one million per year, which represented quite sizeable percentage increases in the United States population. Immigration decreased greatly during World War I and following the adoption of quotas based on national origin in 1921. The economic depression in the 1930's caused an additional but temporary decrease, which resulted in more emigration than immigration. Annual immigration increased after World War II to around 300,000 persons per year and stayed at that level through the 1950's and into the 1960's. With the Immigration Act of 1965 and other related changes, annual immigration increased to about 400,000, although a few years have been somewhat greater because of the influx of refugees. Although statistics on emigration are sparse and highly estimated (see, "Foreign-Born Emigration From the United States: 1960 to 1970" by Warren and Peck in Demography, February 1980), they suggest that annual emigration is over 100,000. For the 1983 Report of the Board of Trustees alternatives I, II, and III, we assumed an annual net immigration (the excess of immigration over emigration) of 450,000, 400,000, and 350,000, respectively. The age-sex distribution shown in Table 10 was based on data supplied by the Immigration and Naturalization Service on immigration during the 1970's.

## 5. Marriage

Data on new marriages in the Marriage Registration Area during calendar years 1957 through 1979 by age of husband crossed with age of wife were obtained from the National Center for Health Statistics. Estimates of the nonmarried population in the Marriage Registration Area (which consists of 41 States and D.C. and accounts for about 80 percent of all marriages in the U.S.) were obtained from the Bureau of the Census by age group and sex. The age distribution of the nonmarried population in the Marriage Registration Area for each age group estimated by the Bureau of the Census was assumed to be the same as the nonmarried population in the Social Security Area.

During the period 1959 through 1979 the age-adjusted marriage rate has ranged from a high in 1959 of 7,573 per hundred thousand nonmarried persons of each sex to a low in 1978 of 4,900 with an average of 6,669. The age-adjusted rate for 1979 was 5,118. Because we are uncertain whether marriage rates will increase or decrease, we assumed that future rates of marriage would remain at the same level as observed during the 12 months ending with June 1982. The age\*of\*husband-age\*of\*wife-specific rates observed in 1979 were adjusted to this level. These rates for five-year age groups are shown in Table 11. Of course, use of constant age-specific rates does not imply that the crude rate of marriage in the projected population remains constant.

Although a complete projection of age\*of\*husband-age\*of\*wife-specific central marriage rates was not done for each previous marital status, we felt that it was important to reflect some differential in marriage rates by previous marital status. Future relative differences in marriage rates by previous marital status were assumed to be as experienced during 1979. These rates were obtained from unpublished data supplied by the National Center for Health Statistics, and with some modifications are given in Table 12.

## 6. Divorce

The unavailability of data for an acceptable representative statistic for divorces precluded us from easily studying past trends in divorce. Hence we assumed that future age\*of\*husband-age\*of\*wife-specific rates of divorce would remain at about the same level as currently observed. Of course, this does not imply that the crude rate of divorce in the projected population remains constant.

Data on divorces (including annulments) in the Divorce Registration Area during calendar year 1979 by age group of husband crossed with age group of wife were obtained from the National Center for Health Statistics. The divorces occurring in the Divorce Registration Area (which consists of 29 States and accounts for about 60 percent of all divorces in the U.S.) were then inflated to represent the Social Security Area, based on the total number of divorces during calendar year 1979 in the fifty States, District of Columbia, Puerto Rico, and the Virgin Islands. Central divorce rates for each age group of

husband crossed with each age group of wife were calculated as the ratio of the number of divorces in the Social Security Area to couples with given ages of husband and wife to the number of existing marriages in the Social Security Area with the given ages of husband and wife. The rates were then adjusted to level observed during the 12 months ending with June 1982 and are shown in Table 13.

## 7. Illegal Aliens

Very little is known about the number of illegal aliens currently residing in the United States. Recent estimates have ranged from 3 million to 12 million, reflecting the lack of data and apparently also the specific interests of the groups that prepared the estimates.

Illegal aliens are included in our starting population, as it is the official policy of the Bureau of the Census to either enumerate or to include in the estimated undercount all persons residing in the United States, whether legally or illegally. It appears that the illegal residents are undercounted to a much larger extent than the legal residents.

The annual net immigration assumed in this study excludes aliens entering the United States illegally, largely because no reliable estimate of their number exists. Part of the problem in analyzing net illegal immigration is that many illegal aliens tend to stay in the United States temporarily rather than permanently, as they frequently return to families in their native countries.

In summary, our starting population includes illegal aliens. Our projections take into account deaths and births to these illegal aliens, but assume no future net illegal immigration.

## C. METHODS

### 1. Probabilities of Survival

To calculate probabilities of survival by age last birthday, life tables for each sex were constructed for each year from 1981 to 2080. The method used was similar to that used for the 1959-61 United States Decennial Life Tables, with some modifications at the very young ages and the older ages. Central death rates based on data from the National Center for Health Statistics were used for ages 0 to 64, while central death rates based on data from the Social Security Medicare program were used for ages 65 to 94. A detailed analysis of Medicare mortality statistics and comparison to NCHS statistics is contained in "Recent Trends in the Mortality of the Aged" by John C. Wilkin in the Transactions of the Society of Actuaries, Volume XXXIII.

The probability of death at each age 0 ( $q_0$ ) was calculated from the population central death rate for age 0 and the relationship between the probability of death and the central death rate that existed in 1978. The probabilities of death at each age 1 through 4 ( $q_1, q_2, q_3, q_4$ ) were calculated from the population central death rate for ages 1 through 4 ( ${}_4m_1$ ) and the relationship between the two that existed in 1978. Probabilities of death for each age 5 through 94 were calculated such that the central death rates for 5 year age groups obtained by weighting the single age central death rates in the table by the population would equal those in the population. The probabilities of death within each single age in each five-year age group from 5-9 to 90-94 was accomplished by interpolating with Beer's minimized fifth-difference formula with smoother ends on the log of the five-year probability of survival. Probabilities of death for each age 95 and over were calculated to produce a rapid decline in the ratio of succeeding probabilities of death to a minimum ratio of 1.05 for females and 1.04 for males. These ratios were chosen after analysis by Francisco R. Bayo and Joseph F. Faber contained in the article "Mortality Experience Around Age 100", in the Transactions of the Society of Actuaries Volume XXXV. For more detail on the method used to produce the life tables for these population projections see Actuarial Study No. 87, "Life Tables For The United States: 1900-2050" by Joseph F. Faber. This study also contains many of the life tables used in the alternative II projection.

For those newly born during the year, the probability of survival was calculated as the ratio of the stationary population at age zero ( $L_0$ ) to the new births ( $t_0$ ). For each age 0 to 99, the probability of survival was calculated as the ratio of the stationary population at the succeeding age ( $L_{x+1}$ ) to the stationary population at the age ( $L_x$ ). For the group aged 100 and over, the probability of survival was calculated as the ratio of the stationary population at ages 101 and over ( $T_{101}$ ) to the stationary population at ages 100 and over ( $T_{100}$ ).

Probabilities of survival by marital status were also calculated from life tables by marital status based on data from the period 1959-61.

## 2. Probabilities of Marriage and Divorce

Probabilities of marriage were calculated for each age of husband crossed with each age of wife from the central marriage rates for calendar year 1979 so as to reproduce a provisional estimate of marriages in the Social Security Area from July 1, 1981 to July 1, 1982. The calculation was necessarily iterative, because the probability of marriage to a partner at a given age is dependent upon the probabilities of marriage to partners of other ages. Probabilities of divorce were calculated for each age group of husband crossed with each age group of wife from the central divorce rates for calendar year 1979 so as to reproduce a provisional estimate of divorces in the Social Security Area from July 1, 1981 to July 1, 1982. The provisional estimates of marriages and divorces were developed from data published by the National Center for Health Statistics in Monthly Vital Statistics Reports Volumes 30 and 31.

## 3. Deaths

The number of deaths occurring at each age and sex was calculated as the difference between the number of people alive at the beginning of the year and the product of the number of people alive at the beginning of the year and the probability of survival. The numbers of deaths were then distributed by marital status in the same proportions as would have been produced by applying the marital-status-specific probabilities of survival to the population by marital status at the beginning of the year. Projected numbers of deaths are given in Table 14 by alternative.

## 4. Marriages

The number of marriages occurring at each age of husband crossed with each age of wife was calculated iteratively as the product of the probability of marriage and the square root of the product of the male population exposed to marriage and the female population exposed to marriage. (The male population exposed to marriage was approximated as the nonmarried male population of the given age at the beginning of the year less one-half of all marriages to partners of ages other than the given age of the female. The female population exposed to marriage was approximated similarly). The numbers of marriages were then distributed by previous marital status in the same proportions as would have been produced by applying the previous-marital-status-specific central marriage rates to the population by marital status at the beginning of the year. Projected numbers of marriages are given in Table 14 by alternative.

## 5. Widowings

The number of marriages dissolved by death at each age of husband crossed with each age of wife was calculated by applying joint-life probabilities of death to the existing marriages by age of husband

crossed with age of wife at the beginning of the year. (The joint-life probabilities were developed to be consistent with the projected death rates and the assumed mortality differential by marital status, and assumed independence of the partners). The numbers of widowings at each age and sex were calculated as the difference between the marriages dissolved by death and the previously calculated deaths to married persons.

#### 6. Divorces

The number of marriages dissolved by divorce at each age of husband crossed with each age of wife was calculated by applying probabilities of divorce to the existing marriages by age of husband crossed with age of wife at the beginning of the year. Projected numbers of divorces are given in Table 14 by alternative.

#### 7. Net Immigration

The assumed net immigration for each age and sex was distributed by marital status in the same proportions as existed in the nonmarried population at the beginning of the year.

#### 8. End of Year Population

The single population at the end of the year for each age and sex was calculated from the single population at the beginning of the year by subtracting the deaths and marriages during the year, and adding the net immigration. The married population at the end of the year was calculated from that at the beginning of the year by subtracting the deaths and divorces, and adding the marriages. The widowed population at the end of the year was calculated by subtracting the deaths and marriages, and adding the widowings and net immigration. The divorced population at the end of the year was calculated by subtracting the deaths and marriages, and adding the divorces and net immigration.

The existing marriages at the end of the year by age of husband crossed with age of wife were calculated from the existing marriages at the beginning of the year by subtracting the marriages dissolved by death and those dissolved by divorce and adding the new marriages during the year. The methods used assured consistency between the married population by age and sex at the end of the year and the existing marriages at the end of the year.

#### 9. Births

Central birth rates covering July 1 to June 30 were approximated from those covering January 1 to December 31 by linear interpolation. These rates were then applied to the average of the beginning of year and end of year female populations to calculate births during the year. Projected numbers of births are given in Table 14 by alternative.

## D. RESULTS

### 1. Total Population

Tables 17, 18, 19 give projections of the Social Security Area population by age group, sex, marital status, and alternative for selected years. Tables 16 give similar figures for historical years. The past and projected total population is shown graphically in Chart 3. Under alternative I (with greater than replacement fertility), the total population increases ever more rapidly from 239 million in 1981 to 455 million in 2080. Under alternative II, the total population increases gradually to 346 million in 2080 as a 2.0 total fertility rate plus 400,000 annual immigrants are slightly more than enough to replenish the population. Under alternative III, the total population increases to 290 million in 2026 and then decreases to 244 million in 2080 because of the accumulated effect of below-replacement fertility and net immigration.

The proportion of the population which is single is projected to be 43 percent in 2080, the same as it was in 1981, under alternative I, to decrease to 38 percent under alternative II, and to 30 percent under alternative III, reflecting differences in the aging of the population among the three alternatives. The proportion married is projected to change from 46 percent in 1981 to 44, 47, and 52 percent in 2080, under alternatives I, II, and III, respectively. The proportion widowed in 2080 is projected to change from 6 percent in 1981 to 7 and 9 percent, under alternatives II and III, respectively and to remain at 6 percent under alternative I. The current high incidence of divorce, which is assumed to continue in the future, causes the proportion divorced to increase greatly from 5 percent in 1981 to 7 percent under alternative I, to 8 percent under alternative II, and to 9 percent under alternative III in 2080.

### 2. Aged Population

The projected population at ages 65 and over is shown in Chart 4. The relative stability in the aged population around the year 2000 under alternative I is caused by the low fertility experienced during the 1930's. Under alternatives II and III, the aged population around the year 2000 grows significantly because of the effect of assumed mortality improvements which are greater than under alternative I. The high fertility of the 1950's and 1960's results in sharp steady growth in the aged population throughout the period 2010-2030 under all of the alternatives. By the year 2080, the aged population as percentage of total population differs greatly among the three alternatives. Under alternative I the percentage of the total population in 2080 who are 65 or over is 16 percent, under alternative II is 22 percent, and under alternative III is 34 percent.

### 3. Demographic Indicators

The projected population is summarized by broad age group and alternative for selected years in Tables 15. The broad age groups are those aged under 20, those aged 20 to 64, and those aged 65 and over. Tables 15 also summarize the projected total population by marital status.

The aged dependency ratio given in Tables 15 is the ratio of the number of persons aged 65 and over to the number of persons aged 20 to 64. This ratio provides an indicator of possible future demographic pressures which may be faced by Social Security, and is shown graphically in Chart 5. Under alternative I, the aged dependency ratio is projected to increase from .196 in 1981 to .333 in the year 2031 and then to decrease to an ultimate level of about .300. Under alternative II, the aged dependency ratio is projected to increase to about .400 by the 2030's and then to stay around that level. Under alternative III, the aged dependency ratio is projected to increase throughout the entire projection period to .685 in the year 2080. A sharp increase in the aged dependency ratio shortly after the turn of the century is certain as the baby boom generation attains age 65 while the baby-bust generation attains age 20. The magnitude of the increase, however, will depend upon future mortality improvements among the aged and future fertility rates. Even under optimistic assumptions the aged dependency ratio will increase nearly 70 percent by the year 2030.

The total dependency ratio given in Tables 15 is the ratio of the number of persons aged 65 and over together with the number of persons under 20 to the number of persons aged 20 to 64. This ratio views from a somewhat larger perspective the possible future financial burdens to be born by workers. Under all three alternatives, total dependency ratio is projected to decrease from .743 in 1981 until shortly after the turn of the century, reflecting both the small number of children resulting from the low fertility rates experienced since 1970 and projected to be experienced in the near future, and also the slow growth in the aged population resulting from the low fertility rates experienced during the 1930's. The existence of this extremely favorable demographic composition is often overlooked because of the attention given to the financial problems expected when the baby-boom generation begins to attain retirement age. Projected values of the total dependency ratio in 2080 range from .840 under alternative I to 1.033 under alternative III or roughly from 10 to 30 percent higher than the 1981 value.

The disunity ratio given in Tables 15 is the ratio of the number of divorced persons to the number of married persons together with the number of widowed persons. This ratio provides an indicator of possible future instability in the institution of marriage. Assuming a continuation of the current high incidence of divorce, this ratio will increase by more than 50 percent by the turn of the century. Chart 6 compares the distribution of the population by marital status in 1981 with the projected distribution in 2080.

49	.0	.0	.0	.0	.0	.0	.0	.0	.0	.0	.0	.0	.0	.0

NOTE: The central birth rate is the ratio of the number of births during the year to mothers at the tabulated age to the midyear female population at that age.

Table 5. Total Fertility Rates, by Calendar Year and Alternative (per thousand women)

Calendar Year	Calendar Year	Calendar Year	Alternative		
			I	II	III
1920	3263.3	1950	3028.0	1849.0	1849.0
1921	3326.2	1951	3199.1	1851.5	1851.5
1922	3109.4	1952	3286.5	1854.9	1854.9
1923	3101.2	1953	3349.4	1873.5	1859.2
1924	3120.7	1954	3461.2	1892.6	1864.4
1925	3011.6	1955	3498.3	1912.0	1869.8
1926	2900.7	1956	3604.7	1931.0	1875.4
1927	2824.3	1957	3682.4	1950.0	1881.6
1928	2659.8	1958	3628.9	1968.8	1887.9
1929	2532.0	1959	3638.2	1987.3	1894.2
1930	2532.5	1960	3605.7	2005.8	1900.5
1931	2401.7	1961	3563.9	2024.1	1906.9
1932	2318.6	1962	3423.3	2042.3	1913.3
1933	2172.0	1963	3297.8	2060.5	1919.6
1934	2232.0	1964	3170.9	2078.6	1925.9
1935	2188.7	1965	2881.6	2096.6	1932.1
1936	2145.6	1966	2670.4	2114.4	1938.2
1937	2173.3	1967	2525.5	2132.0	1944.3
1938	2221.7	1968	2431.0	2149.3	1950.4
1939	2171.7	1969	2422.9	2166.6	1956.3
1940	2229.0	1970	2431.7	2183.8	1962.0
1941	2331.5	1971	2245.4	2200.8	1967.6
1942	2554.8	1972	1993.6	2217.7	1973.2
1943	2640.2	1973	1862.5	2234.5	1978.7
1944	2494.5	1974	1824.4	2251.1	1984.1
1945	2421.8	1975	1770.3	2267.6	1989.4
1946	2857.9	1976	1744.8	2283.8	1994.8
1947	3181.2	1977	1795.0	2300.0	2000.0
1948	3026.2	1978	1764.4		
1949	3036.2	1979	1816.7		

Note: The total fertility rate is the average number of children that would be born to a woman if she were to survive the childbearing period and were to experience the age-specific central birth rates for the tabulated year throughout that period.

Table 6. Average Annual Percentage Improvements in Central Death Rates during 1968-78, by Age, Sex, and Cause of Death

Sex	Age	Total	Cause of Death									
			Heart Disease	Cancer	Vascular Disease	Violence	Respiratory Disease	Infancy	Digestive Disease	Diabetes Mellitus	Liver Cirrhosis	Other
Male	0	5.08	-8.66	2.44	-.45	6.44	14.42	6.01	2.79	7.52	1.76	-3.91
	1-4	2.87	-2.16	4.93	2.53	1.37	10.27	1.70	4.66	9.33	5.96	2.21
